

Nonabelian Discrete Family Symmetry to Soften the SUSY Flavor Problem and to Suppress Proton Decay

Yuji Kajiyama, Etsuko Itou, and Jisuke Kubo

Institute for Theoretical Physics, Kanazawa University, Kanazawa 920-1192, Japan

Abstract

Family symmetry could explain large mixing of the atmospheric neutrinos. The same symmetry could explain why the flavor changing current processes in supersymmetric standard models can be so suppressed. It also may be able to explain why the proton is so stable. We investigate these questions in a supersymmetric, renormalizable extension of the standard model, which possess a family symmetry based on a binary dihedral group Q_6 . We find that the amplitude for $\mu \rightarrow e + \gamma$ enjoys a suppression factor proportional to $|(V_{\text{MNS}})_{e3}| \simeq m_e/(\sqrt{2}m_\mu) \simeq 3.4 \times 10^{-3}$, and that $B(p \rightarrow K^0 \mu^+)/B(p \rightarrow K^0 e^+) \simeq |(V_{\text{MNS}})_{e3}|^2 \simeq 10^{-5}$, where V_{MNS} is the neutrino mixing matrix.

I. INTRODUCTION

The remarkable success of the standard model (SM) suggests that we have a highly non-trivial part of a more fundamental theory for elementary particle physics. In spite of this success, the SM suffers from various problems. One of them is that due to the quadratic divergence of the Higgs mass its natural scale can not exceed $O(1)$ TeV [1]. Therefore, in order to extend the SM in a natural way, the quadratic divergence has to be cancelled [1, 2]. As it is well known today, low energy supersymmetry (SUSY) is introduced to protect the Higgs mass from the quadratic divergence [3, 4]. Unfortunately, SUSY is broken, and therefore its breaking should be soft to maintain the very nature of low energy SUSY, whatever its origin is [3, 4].

Renormalizability allows an introduction of a certain set of soft supersymmetry breaking (SSB) parameters. In the minimal supersymmetric standard model (MSSM), more than 100 SSB parameters can be introduced [5]. Moreover, these parameters should be highly fine tuned so that they do not induce unacceptably large flavor changing neutral currents (FCNCs) and CP violations [6, 7, 8, 9, 10]. Why should they be so fine tuned? What controls them? This is the so-called SUSY flavor problem, which has existed ever since SUSY found phenomenological applications [11].

There are several theoretical approaches to overcome this problem [3, 4][12]-[25]. One of them is to base on a family symmetry [22]-[25]. However, if the family symmetry is hardly broken (i.e. broken by operators with dimension ≥ 4), non-symmetric SSB terms can be generated in higher orders in perturbation theory. Then it is not possible to make quantitative statements on the induced non-symmetric SSB terms, because these terms are infinite in perturbation theory, however small the hard breaking terms are. In this paper, we consider a supersymmetric model, recently proposed in [26], which possesses a nonabelian discrete family symmetry based on a binary dihedral group Q_6 . We investigate how the SUSY flavor problem can be softened by Q_6 family symmetry, which is our first task. We find that except for few cases the fine tuning of the SSB parameters is not necessary in this model. The only observable process would be $\mu \rightarrow e + \gamma$, whose branching fraction enjoys a suppression factor proportional to $|(V_{\text{MNS}})_{e3}|^2 \simeq m_e^2/(2m_\mu^2) \simeq 10^{-5}$, and is three (four) orders of magnitude larger than that of $\tau \rightarrow e(\mu) + \gamma$ in the model, where V_{MNS} is the neutrino mixing matrix.

In the MSSM without R parity invariance, there exist about 100 dimension-four operators that violate the baryon number or lepton number conservations. Fortunately, R invariance can kill all these dangerous dimension-four operators, while it together with $B - L$ conservation allows two types of dimension-five operators that lead to proton decay [27, 28]. It is therefore widely expected that these operators are responsible for an observable proton decay. Indeed, in the minimal SUSY grand unified theory (GUT) based on $SU(5)$ [11], these operators force protons to decay faster than the experimental bound [29]. Given a family symmetry, the flavor structure is fixed, at least partially, and it can control the flavor

changing effects in proton decay, too [30]. In this paper we assume that some unknown Planck scale physics, which respects Q_6 family symmetry, induces dimension-five operators that lead to proton decay. We first would like to find out all B and L violating operators with dimension ≤ 5 allowed by Q_6 , and then to investigate how the family symmetry acts on proton decay. If we assume the degeneracy of the scalar quark masses, then the branching fraction $B(p \rightarrow K^0 e^+)$ is similar to that of [30] that it becomes comparable with $B(p \rightarrow K^+ \bar{\nu})$. If the degeneracy assumption is dropped, $B(p \rightarrow K^0 e^+)$ can become $O(10^{-4}) \times B(p \rightarrow K^+ \bar{\nu})$, which is still two orders of magnitude larger than that of the minimal SUSY GUT case. It turns out that in contrast to the case of [30] the branching fraction $B(p \rightarrow K^0 \mu^+)$, which turns out to be proportional to $|(V_{\text{MNS}})_{e3}|^2$, is five orders of magnitude smaller than $B(p \rightarrow K^0 e^+)$ in the present case, irrespective of the degeneracy of the scalar quark masses. The main reason for this is the maximal mixing in the charged lepton sector, which serves the maximal mixing of the atmospheric neutrinos in this model. We also give an upper bound on the coupling constants that are assumed to be generated by Planck scale physics. We find that the family symmetry can raise the upper bound by two orders of magnitude.

In sect. II we outline the model of [26]. Because of the nonabelian family symmetry, the Yukawa sector of the model is strongly constrained, and the redundancy of the parameters of this sector is significantly reduced. As a consequence, we can explicitly give the unitary matrices, U_L and U_R , that rotate the left and right-handed fermions to diagonalize the corresponding mass matrices. They are needed to quantitatively discuss the SUSY flavor problem in the super CKM basis in sect. III. For completeness, we re-present the predictions from Q_6 family symmetry. In sect. IV we consider the B and L violating operators that are allowed by the family symmetry and then calculate the dominant proton decay modes as function of superpartner masses. We conclude in sect. V.

II. THE MODEL

A. Group theory of Q_{2N}

The binary dihedral group Q_{2N} ($N = 2, 3, \dots$) is a finite subgroup of $SU(2)$ ¹.

Its defining matrices are given by [26, 31]

$$\tilde{R}_{2N} = \begin{pmatrix} \cos \frac{\theta_N}{2} & \sin \frac{\theta_N}{2} \\ -\sin \frac{\theta_N}{2} & \cos \frac{\theta_N}{2} \end{pmatrix}, \quad \tilde{P}_Q = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad (1)$$

where $\theta_N = 2\pi/N$. Then the set of $4N$ elements of Q_{2N} is given by

$$\mathcal{G}_{Q_{2N}} = \{\tilde{R}_{2N}, (\tilde{R}_{2N})^2, \dots, (\tilde{R}_{2N})^{2N} = \mathbf{1}, \tilde{R}_{2N}\tilde{P}_Q, (\tilde{R}_{2N})^2\tilde{P}_Q, \dots, (\tilde{R}_{2N})^{2N}\tilde{P}_Q = \tilde{P}_Q\}. \quad (2)$$

¹ Models based on dihedral flavor symmetries, ranging from $D3(\simeq S_3)$ to Q_6 and D_7 , have been recently discussed in [26], [31]-[37].

Only one- and two-dimensional irreps. exist. There exist four different one-dimensional irreps of Q_{2N} , which can be characterized according to $Z_2 \times Z_4$ charge:

$$\begin{aligned} \mathbf{1}_{+,0}, \quad \mathbf{1}_{-,0}, \quad \mathbf{1}_{+,2}, \quad \mathbf{1}_{-,2} \quad \text{for } N = 2, 4, 6, \dots, \\ \mathbf{1}_{+,0}, \quad \mathbf{1}_{-,1}, \quad \mathbf{1}_{+,2}, \quad \mathbf{1}_{-,3} \quad \text{for } N = 3, 5, 7, \dots, \end{aligned} \quad (3)$$

where the $\mathbf{1}_{+,0}$ is the true singlet of Q_{2N} , and only $\mathbf{1}_{-,1}$ and $\mathbf{1}_{-,3}$ are complex irreps. The $N - 1$ different two-dimensional irreps are denoted by

$$\mathbf{2}_\ell, \quad \ell = 1, \dots, N - 1. \quad (4)$$

$\mathbf{2}_\ell$ with odd ℓ is a pseudo real representation, while $\mathbf{2}_\ell$ with even ℓ is a real representation. It is straightforward to calculate the Clebsch-Gordan coefficients for tensor products of irreps. The following multiplication rules in Q_6 in particular are used to construct the model [26].

$$\begin{aligned} \mathbf{2}_2 \times \mathbf{2}_2 &= \mathbf{1}_{+,0} + \mathbf{1}_{+,2} + \mathbf{2}_2 \\ \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} \times \begin{pmatrix} b_1 \\ b_2 \end{pmatrix} &= (a_1 b_1 + a_2 b_2) \quad (a_1 b_2 - a_2 b_1) \quad \begin{pmatrix} -a_1 b_1 + a_2 b_2 \\ a_1 b_2 + a_2 b_1 \end{pmatrix}, \end{aligned} \quad (5)$$

$$\begin{aligned} \mathbf{2}_1 \times \mathbf{2}_2 &= \mathbf{1}_{-,3} + \mathbf{1}_{-,1} + \mathbf{2}_1 \\ \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \times \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} &= (x_1 a_2 + x_2 a_1) \quad (x_1 a_1 - x_2 a_2) \quad \begin{pmatrix} x_1 a_1 + x_2 a_2 \\ x_1 a_2 - x_2 a_1 \end{pmatrix}. \end{aligned} \quad (6)$$

B. Q_6 assignment and superpotential

In Table I we write the Q_6 assignment of the quark, lepton and Higgs chiral supermultiplets², where Q, Q_3, L, L_3 and H^u, H_3^u, H^d, H_3^d stand for $SU(2)_L$ doublets supermultiplets for quarks, leptons and Higgs bosons, respectively. Similarly, $SU(2)_L$ singlet supermultiplets for quarks, charged leptons and neutrinos are denoted by $U^c, U_3^c, D^c, D_3^c, E^c, E_3^c$ and N^c, N_3^c . S, T and Y are $SU(3)_C \times SU(2)_L \times U(1)_Y$ singlet Higgs supermultiplets. As an alternative

to the abelian discrete R symmetry Z_{12R} of [26], for which one needs more singlets to construct a desired Higgs sector, we introduce an abelian Z_4 symmetry. The Z_4 constrains the Higgs sector, where it does not constrain anything in the Yukawa sector. When discussing proton decay in sect. IV, we will assume neither Z_4 nor Z_{12R} , because the symmetry of the Higgs sector may have a stronger model dependence. We then write down the most general, renormalizable, $Q_6 \times Z_4 \times R$ invariant superpotential W :

$$W = W_Q + W_L + W_H, \quad (7)$$

² The same model exists for Q_{2N} if N is odd and a multiple of 3.

	Q	Q_3	U^c, D^c	U_3^c, D_3^c	L	L_3	E^c, N^c	E_3^c	N_3^c	H^u, H^d	H_3^u, H_3^d	S	T	Y
Q_6	$\mathbf{2}_1$	$\mathbf{1}_{+,2}$	$\mathbf{2}_2$	$\mathbf{1}_{-,1}$	$\mathbf{2}_2$	$\mathbf{1}_{+,0}$	$\mathbf{2}_2$	$\mathbf{1}_{+,0}$	$\mathbf{1}_{-,3}$	$\mathbf{2}_2$	$\mathbf{1}_{-,1}$	$\mathbf{2}_1$	$\mathbf{2}_2$	$\mathbf{1}_{+,2}$
Z_4	3	3	0	0	1	1	2	2	2	1	1	2	2	0
R	—	—	—	—	—	—	—	—	—	+	+	+	+	+

TABLE I: $Q_6 \times Z_4 \times R$ assignment of the chiral supermultiplets, where R is the R parity. This is an alternative assignment to the one given in [26]. The abelian Z_4 is also an alternative to the abelian discrete R symmetry Z_{12R} [26], for which one needs more singlets to construct a desired Higgs sector. The anomalies, $Q_6[SU(2)_L]^2$, $Q_6[SU(3)_C]^2$, $Z_4[SU(2)_L]^2$ and $Z_4[SU(3)_C]^2$, can be cancelled by the Green-Schwarz mechanism if, for instance, $\kappa_2 = \kappa_3$ is satisfied [38], where κ_2 and κ_3 are the Kac-Moody levels for $SU(2)_L$ and $SU(3)_C$, respectively.

where

$$W_Q = \sum_{I,i,j,k=1,2,3} (Y_{ij}^{uI} Q_i U_j^c H_I^u + Y_{ij}^{dI} Q_i D_j^c H_I^d), \quad (8)$$

$$W_L = \sum_{I,i,j,k=1,2,3} (Y_{ij}^{eI} L_i E_j^c H_I^d + Y_{ij}^{\nu I} L_i N_j^c H_I^u) + \frac{m_N}{2} \sum_{i=1,2} (N_i^c)^2 + \frac{\lambda_N}{2} (N_3^c)^2 Y, \quad (9)$$

$$\begin{aligned} W_H = & m_T(T_1^2 + T_2^2) + m_Y Y^2 + \lambda_S(S_1^2 + S_2^2)Y \\ & + \lambda_1(H_1^u S_2 + H_2^u S_1)H_3^d + \lambda_2(H_1^d S_2 + H_2^d S_1)H_3^u \\ & + \lambda_3 [-(H_1^u H_1^d - H_2^u H_2^d)T_1 + (H_1^u H_2^d + H_2^u H_1^d)T_2]. \end{aligned} \quad (10)$$

The Yukawa matrices Y 's are given by

$$\begin{aligned} \mathbf{Y}^{u1(d1)} &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & Y_b^{u(d)} \\ 0 & Y_{b'}^{u(d)} & 0 \end{pmatrix}, \quad \mathbf{Y}^{u2(d2)} = \begin{pmatrix} 0 & 0 & Y_b^{u(d)} \\ 0 & 0 & 0 \\ -Y_{b'}^{u(d)} & 0 & 0 \end{pmatrix}, \\ \mathbf{Y}^{u3(d3)} &= \begin{pmatrix} 0 & Y_c^{u(d)} & 0 \\ Y_c^{u(d)} & 0 & 0 \\ 0 & 0 & Y_a^{u(d)} \end{pmatrix}, \end{aligned} \quad (11)$$

$$\mathbf{Y}^{e1} = \begin{pmatrix} -Y_c^e & 0 & Y_b^e \\ 0 & Y_c^e & 0 \\ Y_{b'}^e & 0 & 0 \end{pmatrix}, \quad \mathbf{Y}^{e2} = \begin{pmatrix} 0 & Y_c^e & 0 \\ Y_c^e & 0 & Y_b^e \\ 0 & Y_{b'}^e & 0 \end{pmatrix}, \quad \mathbf{Y}^{e3} = 0, \quad (12)$$

$$\begin{aligned} \mathbf{Y}^{\nu 1} &= \begin{pmatrix} -Y_c^\nu & 0 & 0 \\ 0 & Y_c^\nu & 0 \\ Y_{b'}^\nu & 0 & 0 \end{pmatrix}, \quad \mathbf{Y}^{\nu 2} = \begin{pmatrix} 0 & Y_c^\nu & 0 \\ Y_c^\nu & 0 & 0 \\ 0 & Y_{b'}^\nu & 0 \end{pmatrix}, \\ \mathbf{Y}^{\nu 3} &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & Y_a^\nu \end{pmatrix}. \end{aligned} \quad (13)$$

All the parameters appearing above are real, because we assume a spontaneous CP violation to occur. We will shortly come back to this issue.

The Z_4 charges of the fields are so chosen that the most general $Q_6 \times Z_4 \times R$ invariant Higgs superpotential (10) has an accidental symmetry:

$$H_1^{u,d} \leftrightarrow H_2^{u,d}, S_1 \leftrightarrow S_2, T_1 \rightarrow -T_1, \quad (14)$$

where $H_3^{u,d}$, T_2 and Y do not transform. This symmetry ensures the stability of the VEV structure

$$\begin{aligned} \langle H_1^u \rangle &= \langle H_2^u \rangle = \frac{1}{2} v_D^u e^{i\theta^u}, \quad \langle H_1^d \rangle = \langle H_2^d \rangle = \frac{1}{2} v_D^d e^{i\theta^d}, \quad \langle H_3^{u,d} \rangle = \frac{1}{\sqrt{2}} v_3^{u,d} e^{i\theta_3^{u,d}}, \\ \langle S_1 \rangle &= \langle S_2 \rangle = v^S e^{i(\theta^S/2)}, \quad \langle T_2 \rangle = v^T e^{i(\theta^T/2)}, \quad \langle Y \rangle = v^Y e^{i(\theta^Y/2)}, \quad \langle T_1 \rangle = 0, \end{aligned} \quad (15)$$

where v 's are non-vanishing real quantities.

The total Higgs potential consists of the supersymmetric part (D terms and F terms) and the $Q_6 \times Z_4 \times R$ invariant SSB part, where the B and A terms are given by

$$\begin{aligned} \mathcal{L}_{\text{SSB}}^H &= B_T(\tilde{T}_1^2 + \tilde{T}_2^2) + B_Y \tilde{Y}^2 + \lambda_S A_S(\tilde{S}_1^2 + \tilde{S}_2^2) \tilde{Y} \\ &\quad + \lambda_1 A_1(\tilde{H}_1^u \tilde{S}_2 + \tilde{H}_2^u \tilde{S}_1) \tilde{H}_3^d + \lambda_2 A_2(\tilde{H}_1^d \tilde{S}_2 + \tilde{H}_2^d \tilde{S}_1) \tilde{H}_3^u \\ &\quad + \lambda_3 A_3 \left[-(\tilde{H}_1^u \tilde{H}_1^d - \tilde{H}_2^u \tilde{H}_2^d) \tilde{T}_1 + (\tilde{H}_1^u \tilde{H}_2^d + \tilde{H}_2^u \tilde{H}_1^d) \tilde{T}_2 \right] + h.c. \end{aligned} \quad (16)$$

(The fields with a tilde are the bosonic components of the corresponding supermultiplets.) As in the case of the supersymmetric part, B 's and A 's are assumed to be real. We have investigated the minimization conditions for the angles θ 's given in (15), and found that a nontrivial solution of the conditions can exist. How the mass spectrum for this nontrivial solution looks like is still an open problem. A complete analysis of this problem, which is similar to that of [39], will go beyond the scope of the present paper. We will publish the analysis elsewhere. To proceed, we here simply assume that there exist a nontrivial CP violating set of VEV's.

C. Fermion mass matrices and diagonalization

We assume that VEVs take the form (15), from which we obtain the fermion mass matrices.

1. Quark sector

The quark mass matrices are given by

$$\mathbf{m}^u = \frac{1}{2} \begin{pmatrix} 0 & \sqrt{2}Y_c^u v_3^u e^{-i\theta_3^u} & Y_b^u v_D^u e^{-i\theta^u} \\ \sqrt{2}Y_c^u v_3^u e^{-i\theta_3^u} & 0 & Y_b^u v_D^u e^{-i\theta^u} \\ -Y_{b'}^u v_D^u e^{-i\theta^u} & Y_{b'}^u v_D^u e^{-i\theta^u} & \sqrt{2}Y_a^u v_3^u e^{-i\theta_3^u} \end{pmatrix}, \quad (17)$$

$$\mathbf{m}^d = \frac{1}{2} \begin{pmatrix} 0 & \sqrt{2}Y_c^d v_3^d e^{-i\theta_3^d} & Y_b^d v_D^d e^{-i\theta^d} \\ \sqrt{2}Y_c^d v_3^d e^{-i\theta_3^d} & 0 & Y_b^d v_D^d e^{-i\theta^d} \\ -Y_{b'}^d v_D^d e^{-i\theta^d} & Y_{b'}^d v_D^d e^{-i\theta^d} & \sqrt{2}Y_a^d v_3^d e^{-i\theta_3^d} \end{pmatrix}. \quad (18)$$

In the present case, the unitary matrices that rotate quarks have the following form: $U_{uL(R)} = R_{L(R)} P_{L(R)}^u O_{L(R)}^u$, where O 's are orthogonal matrices, and

$$R_L = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 & 0 \\ -1 & 1 & 0 \\ 0 & 0 & \sqrt{2} \end{pmatrix}, \quad R_R = \frac{1}{\sqrt{2}} \begin{pmatrix} -1 & -1 & 0 \\ -1 & 1 & 0 \\ 0 & 0 & \sqrt{2} \end{pmatrix}, \quad (19)$$

$$P_L^u = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \exp(i2\Delta\theta^u) & 0 \\ 0 & 0 & \exp(i\Delta\theta^u) \end{pmatrix}, \quad (20)$$

$$P_R^u = \begin{pmatrix} \exp(i2\Delta\theta^u) & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \exp(i\Delta\theta^u) \end{pmatrix} \exp(i\theta_3^u), \quad (21)$$

$$\Delta\theta^u = \theta_3^u - \theta^u, \quad (22)$$

and similarly for the down sector. The phase matrices $P_{L,R}^{u,d}$ can rotate away the phases of the mass matrices, so that we can bring $\mathbf{m}^u$ into a real form

$$\hat{\mathbf{m}}^u = P_L^{u\dagger} R_L^T \mathbf{m}^u R_R P_R^u = m_t \begin{pmatrix} 0 & q_u/y_u & 0 \\ -q_u/y_u & 0 & b_u \\ 0 & b'_u & y_u^2 \end{pmatrix}, \quad (23)$$

which can be then diagonalized as ³

$$O_L^{uT} \hat{\mathbf{m}}^u O_R^u = \begin{pmatrix} m_u & 0 \\ 0 & m_c & 0 \\ 0 & 0 & m_t \end{pmatrix}, \quad (24)$$

and similarly for $\mathbf{m}^d$.

The CKM matrix V_{CKM} is given by

$$V_{\text{CKM}} = O_L^{uT} P_L^{u\dagger} P_L^d O_L^d, \quad (25)$$

³ The form of the mass matrix is known as the next-neighbor interaction form [40, 41].

and for the set of the parameters

$$\begin{aligned}\theta_q &= \theta_3^d - \theta^d - \theta_3^u + \theta^u = -1.25, q_u = 0.0002143, b_u = 0.04443, b'_u = 0.09338, \\ y_u &= 0.99732, q_d = 0.005091, b_d = 0.02570, b'_d = 0.77606, y_d = 0.7940,\end{aligned}\quad (26)$$

we obtain

$$\begin{aligned}m_u/m_t &= 1.10 \times 10^{-5}, m_c/m_t = 4.16 \times 10^{-3}, m_d/m_b = 1.22 \times 10^{-3}, m_s/m_b = 2.13 \times 10^{-2}, \\ |V_{\text{CKM}}| &= \begin{pmatrix} 0.9747 & 0.2236 & 0.0040 \\ 0.2234 & 0.9738 & 0.0421 \\ 0.0093 & 0.0413 & 0.9991 \end{pmatrix}, \quad \sin 2\beta(\phi_1) = 0.738.\end{aligned}\quad (27)$$

The experimental values to be compared are [42]:

$$\begin{aligned}|V_{\text{CKM}}^{\text{exp}}| &= \begin{pmatrix} 0.9739 \text{ to } 0.9751 & 0.221 \text{ to } 0.227 & 0.0029 \text{ to } 0.0045 \\ 0.221 \text{ to } 0.227 & 0.9730 \text{ to } 0.9744 & 0.039 \text{ to } 0.044 \\ 0.0048 \text{ to } 0.014 & 0.037 \text{ to } 0.043 & 0.9990 \text{ to } 0.9992 \end{pmatrix}, \\ \sin 2\beta(\phi_1) &= 0.736 \pm 0.049.\end{aligned}\quad (28)$$

The quark masses at M_Z are given by [43]

$$\begin{aligned}m_u/m_d &= 0.541 \pm 0.086 \text{ (0.61)}, \quad m_s/m_d = 18.9 \pm 1.6 \text{ (17.5)}, \\ m_c &= 0.73 \pm 0.17 \text{ (0.72) GeV}, \quad m_s = 0.058 \pm 0.015 \text{ (0.062) GeV}, \\ m_t &= 175 \pm 6 \text{ GeV}, \quad m_b = 2.91 \pm 0.07 \text{ GeV},\end{aligned}\quad (29)$$

where the values in the parentheses are the theoretical values obtained from (27) for $m_t = 174$ GeV and $m_b = 2.9$ GeV. So, we see that the model can well reproduce the experimentally measured parameters. Because of the family symmetry, the CKM parameters and the quark masses are related. In Fig. 1 we plot the predicted area in the $\sin 2\phi_1 - \phi_3$ plane. We see

FIG. 1: Predicted area in the $\sin 2\phi_1 - \phi_3$ plane. The vertical and horizontal lines correspond to the experimental values, $\sin 2\phi_1(\beta) = 0.726 \pm 0.037$ and $\phi_3 = (60^\circ \pm 14^\circ)$ [42, 44].

from Fig. 1 that the model requires

$$\phi_3 \gtrsim 68^\circ. \quad (30)$$

Another quantity to be compared may be $|V_{td}/V_{ts}|$, whose experimental value has been recently obtained from the observation of $b \rightarrow d + \gamma$ in the B decays [45]:

$$\begin{aligned} \text{Model : } |V_{td}/V_{ts}| &= 0.21 - 0.23, \\ \text{Exp. : } |V_{td}/V_{ts}| &= 0.200^{+0.026}_{-0.025} (\text{exp.})^{+0.038}_{-0.029} (\text{theo.}). \end{aligned} \quad (31)$$

We may conclude that 9 independent parameters of the model can well describe 10 physical observables.

The mass matrices given in the present model can be analytically diagonalized [46], and the approximate formula for V_{CKM} implies that

$$\begin{aligned} V_{us} &\simeq 0.794 \sqrt{\frac{m_d}{m_s}} - \sqrt{\frac{m_u}{m_c}} e^{-i2.5}, \quad V_{cd} \simeq -\sqrt{\frac{m_u}{m_c}} + 0.794 \sqrt{\frac{m_d}{m_s}} e^{-i2.5}, \\ V_{cb} &\simeq 0.81 \left(\frac{m_s}{m_b}\right) e^{-i2.5} - 9.63 \left(\frac{m_c}{m_t}\right) e^{-i1.25}, \end{aligned} \quad (32)$$

which should be compared with the Fritzsch formulas [41].

Finally, we give the unitary matrices that rotate the quarks for the choice of the parameters given in (26):

$$U_{uL(R)} = R_{L(R)}^u P_{L(R)}^u O_{L(R)}^u, \quad U_{dL(R)} = R_{L(R)}^d P_{L(R)}^d O_{L(R)}^d, \quad (33)$$

where $R_{L,R}^u$ and $R_{L,R}^d$ are given in (19) and (20), and

$$O_L^u \simeq \begin{pmatrix} 0.9987 & 0.0514 & 2 \times 10^{-5} \\ 0.0513 & -0.9977 & 0.0442 \\ -0.0023 & 0.0442 & 0.9990 \end{pmatrix}, \quad O_R^u \simeq \begin{pmatrix} -0.9987 & 0.0515 & -10^{-5} \\ 0.0513 & 0.9943 & 0.0933 \\ -0.0048 & -0.0932 & 0.9956 \end{pmatrix}, \quad (34)$$

$$O_L^d \simeq \begin{pmatrix} 0.9834 & 0.1814 & 0.0050 \\ 0.1813 & -0.9833 & 0.0162 \\ -0.0078 & 0.0150 & 0.9999 \end{pmatrix}, \quad O_R^d \simeq \begin{pmatrix} -0.9552 & 0.2960 & -0.0001 \\ 0.1866 & 0.6025 & 0.7760 \\ -0.2298 & -0.7412 & 0.6308 \end{pmatrix}. \quad (35)$$

Using these orthogonal matrices and the matrices defined in (19) ~ (22), Eq. (33) gives the

unitary matrices in the explicit form:

$$\begin{aligned}
U_{uL} &= \begin{pmatrix} 0.706 & 0.0363 & 1.42 \times 10^{-5} \\ -0.706 & -0.0363 & -1.42 \times 10^{-5} \\ 0 & 0 & 0 \end{pmatrix}, \\
&+ e^{2i\Delta\theta^u} \begin{pmatrix} 0.0363 & -0.705 & 0.0313 \\ 0.0363 & -0.705 & 0.0313 \\ -0.00229 e^{-i\Delta\theta^u} & 0.0442 e^{-i\Delta\theta^u} & 0.999 e^{-i\Delta\theta^u} \end{pmatrix}, \tag{36}
\end{aligned}$$

$$\begin{aligned}
U_{dL} &= \begin{pmatrix} 0.695 & 0.128 & 0.00352 \\ -0.695 & -0.128 & -0.00352 \\ 0 & 0 & 0 \end{pmatrix}, \\
&+ e^{2i\Delta\theta^d} \begin{pmatrix} 0.128 & -0.695 & 0.0115 \\ 0.128 & -0.695 & 0.0115 \\ -0.00783 e^{-i\Delta\theta^d} & 0.0150 e^{-i\Delta\theta^d} & 1.00 e^{-i\Delta\theta^d} \end{pmatrix}, \tag{37}
\end{aligned}$$

$$\begin{aligned}
U_{uR} &= e^{i\theta_3^u} \begin{pmatrix} 0.0363 & 0.703 & 0.0660 \\ 0.0363 & 0.703 & 0.0660 \\ 0 & 0 & 0 \end{pmatrix} \\
&+ e^{2i\Delta\theta^u + i\theta_3^u} \begin{pmatrix} -0.706 & 0.0364 & -6.72 \times 10^{-6} \\ 0.706 & -0.0364 & 6.72 \times 10^{-6} \\ -0.00482 e^{-i\Delta\theta^u} & -0.0932 e^{-i\Delta\theta^u} & 0.996 e^{-i\Delta\theta^u} \end{pmatrix}, \tag{38}
\end{aligned}$$

$$\begin{aligned}
U_{dR} &= e^{i\theta_3^d} \begin{pmatrix} 0.132 & 0.426 & 0.549 \\ 0.132 & 0.426 & 0.549 \\ 0 & 0 & 0 \end{pmatrix} \\
&+ e^{2i\Delta\theta^d + i\theta_3^d} \begin{pmatrix} -0.675 & 0.209 & -7.35 \times 10^{-5} \\ 0.675 & -0.209 & 7.35 \times 10^{-5} \\ -0.230 e^{-i\Delta\theta^d} & -0.741 e^{-i\Delta\theta^d} & 0.631 e^{-i\Delta\theta^d} \end{pmatrix}. \tag{39}
\end{aligned}$$

The unitary matrices above will be used when discussing the SUSY flavor problem in sect. III and proton decay in sect. IV.

2. Lepton sector

The mass matrices in the lepton sectors are:

$$\mathbf{m}^e = \frac{1}{2} \begin{pmatrix} -Y_c^e & Y_c^e & Y_b^e \\ Y_c^e & Y_c^e & Y_b^e \\ Y_{b'}^e & Y_{b'}^e & 0 \end{pmatrix} v_D^d e^{-i\theta^d}, \tag{40}$$

$$\mathbf{m}^\nu = \frac{1}{2} \begin{pmatrix} -Y_c^\nu & Y_c^\nu & 0 \\ Y_c^\nu & Y_c^\nu & 0 \\ Y_{b'}^\nu & Y_{b'}^\nu & \sqrt{2} Y_a^\nu \tan \gamma^u e^{i(\theta_3^u - \theta^u)} \end{pmatrix} v_D^u e^{i\theta^u}, \tag{41}$$

where $\tan \gamma^u = v_3^u/v_D^u$. We start with the mass matrix of the charged leptons $\mathbf{m}^e$:

$$U_{eL}^\dagger \mathbf{m}^e U_{eR} = \begin{pmatrix} m_e & 0 & 0 \\ 0 & m_\mu & 0 \\ 0 & 0 & m_\tau \end{pmatrix}. \quad (42)$$

One finds [?] that U_{eL} and U_{eR} can be approximately written as

$$U_{eL} = R \begin{pmatrix} -\epsilon_e(1 + \epsilon_\mu^2) & -(1/\sqrt{2})(1 - \epsilon_e^2 - \epsilon_e^2 \epsilon_\mu^2) & 1/\sqrt{2} \\ \epsilon_e(1 - \epsilon_\mu^2) & (1/\sqrt{2})(1 - \epsilon_e^2 + \epsilon_e^2 \epsilon_\mu^2) & 1/\sqrt{2} \\ 1 - \epsilon_e^2 & -\sqrt{2}\epsilon_e & \sqrt{2}\epsilon_e \epsilon_\mu^2 \end{pmatrix}, \quad (43)$$

$$U_{eR} = R \begin{pmatrix} 1 - \epsilon_\mu^2/2 & -\epsilon_e^2(1 - \epsilon_\mu^2) & \epsilon_\mu \\ -\epsilon_e^2(1 - \epsilon_\mu^2/2) & -1 & 0 \\ -\epsilon_\mu & \epsilon_e^2 \epsilon_\mu & 1 - \epsilon_\mu^2/2 \end{pmatrix} e^{i\theta^d}, \quad (44)$$

where R interchanges the first and second row,

$$R = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad (45)$$

and $\epsilon_\mu = m_\mu/m_\tau$ and $\epsilon_e = m_e/(\sqrt{2}m_\mu)$. In the limit $m_e = 0$, the unitary matrix U_{eL} becomes

$$\begin{pmatrix} 0 & 1/\sqrt{2} & 1/\sqrt{2} \\ 0 & -1/\sqrt{2} & 1/\sqrt{2} \\ 1 & 0 & 0 \end{pmatrix},$$

which is the origin for a maximal mixing of the atmospheric neutrinos.

As for the neutrino masses, we assume that a see-saw mechanism [47] takes place. As we can see from (9), the mass matrix for the right-handed neutrinos is diagonal: $\mathbf{m}_N = ((-1)^\eta m_N, (-1)^\eta m_N, \lambda_N v^Y \exp(i\theta_Y/2))$, ($\eta = 0$ or 1), where m_N and $\lambda_N v^Y$ are real and positive by assumption. Therefore, the Majorana mass matrix for the left-handed neutrinos becomes

$$\begin{aligned} \mathbf{M}_\nu &= \mathbf{m}^\nu \mathbf{m}_N^{-1} (\mathbf{m}^\nu)^T \\ &= (-1)^\eta e^{i2\theta^u} R \begin{pmatrix} 2(\rho_2)^2 & 0 & 2\rho_2\rho_4 \\ 0 & 2(\rho_2)^2 & 0 \\ 2\rho_2\rho_4 & 0 & 2(\rho_4)^2 + (\rho_3)^2 \exp i2\varphi_3 \end{pmatrix} R, \end{aligned} \quad (46)$$

where R is given in (45), and

$$2\varphi_3 = 2(\theta_3^u - \theta^u) + \eta\pi - \theta^Y/2, \quad (47)$$

$$\rho_2 = \frac{1}{2} Y_c^\nu v_D^u / \sqrt{m_N}, \quad \rho_4 = \frac{1}{2} Y_{b'}^\nu v_D^u / \sqrt{m_N}, \quad \rho_3 = \frac{1}{\sqrt{2}} Y_a^\nu v_3^u / \sqrt{Y_N v^Y}. \quad (48)$$

The factor $(-1)^\eta e^{i2\theta^u}$ has no effect, and so we ignore it in the following discussions.

Noticing that the ρ 's in (46) are real numbers, we recall that that $\mathbf{M}_\nu$ can be diagonalized as [34]

$$U_\nu^T \mathbf{M}_\nu U_\nu = \begin{pmatrix} m_{\nu_1} & 0 & 0 \\ 0 & m_{\nu_2} & 0 \\ 0 & 0 & m_{\nu_3} \end{pmatrix}, \quad (49)$$

where $c_{12} = \cos \theta_{12}$, and $s_{12} = \sin \theta_{12}$, and

$$U_\nu = R \begin{pmatrix} -s_{12}e^{i(\phi_\nu - i\varphi_1)/2} & c_{12}e^{i(\phi_\nu - i\varphi_2)/2} & 0 \\ 0 & 0 & -1 \\ c_{12}e^{-i(\phi_\nu + i\varphi_1)/2} & s_{12}e^{-i(\phi_\nu + i\varphi_2)/2} & 0 \end{pmatrix}, \quad (50)$$

$$m_{\nu_3} \sin \phi_\nu = m_{\nu_2} \sin \varphi_2 = m_{\nu_1} \sin \varphi_1, \quad 2\varphi_3 = \varphi_1 + \varphi_2, \quad (51)$$

$$\frac{m_{\nu_2}^2}{\Delta m_{23}^2} \simeq \frac{1}{\sin^2 2\theta_{12} \cos^2 \phi_\nu} - \tan^2 \phi_\nu \quad \text{for } |r| < 1. \quad (52)$$

It turns out that only an inverted mass spectrum

$$m_{\nu_3} < m_{\nu_1}, m_{\nu_2} \quad (53)$$

is consistent with the experimental constraint $|\Delta m_{21}^2| < |\Delta m_{23}^2|$ in the present model. Note that Eq. (51) is satisfied for

$$2\varphi_3 = \varphi_1 + \varphi_2 \sim \pm\pi \quad (54)$$

and not for $\varphi_1 \sim \varphi_2$.

The mixing matrix V_{MNS} can be obtained from $U_{eL}^\dagger U_\nu$, where U_{eL} and U_ν are given in (43) and (50), respectively. The product $U_{eL}^\dagger U_\nu$ can be brought by an appropriate phase transformation to a popular form, which in the present model approximately assumes the form

$$V_{\text{MNS}} \simeq \begin{pmatrix} c_{12} & s_{12} & s_{13}e^{-i\delta} \\ -s_{12}/\sqrt{2} & c_{12}/\sqrt{2} & 1/\sqrt{2} \\ s_{12}/\sqrt{2} & -c_{12}/\sqrt{2} & 1/\sqrt{2} \end{pmatrix} \times \begin{pmatrix} 1 & 0 & 0 \\ 0 & e^{i\alpha} & 0 \\ 0 & 0 & e^{i\beta} \end{pmatrix}. \quad (55)$$

with

$$s_{13} \simeq \epsilon_e = \frac{m_e}{\sqrt{2}m_\mu} = 3.4 \cdots \times 10^{-3}, \quad \delta_{CP} \simeq -\phi_\nu, \quad (56)$$

$$\sin 2\alpha = \sin(\varphi_1 - \varphi_2), \quad \sin 2\beta = \sin(\varphi_1 - \varphi_\nu), \quad (57)$$

where φ_1, φ_2 and ϕ_ν are defined in (51) ⁴. There are seven independent parameters to describe 12 parameters ($3 + 3 = 6$ masses, three angles and three phases) of the lepton

⁴ Unfortunately, this value of s_{13} is too small to be measured [48].

sector. Therefore, the effective Majorana mass $\langle m_{ee} \rangle$ in neutrinoless double β decay, for instance, can be predicted. In Fig. 2 we plot $\langle m_{ee} \rangle$ as a function of $\sin \phi_\nu$ for $\sin^2 \theta_{12} = 0.3$, $\Delta m_{21}^2 = 6.9 \times 10^{-5} \text{ eV}^2$ and $\Delta m_{23}^2 = 1.4, 2.3, 3.0 \times 10^{-3} \text{ eV}^2$ [49]. As we see from Fig. 2, the prediction is consistent with recent experiments [50, 51].

We will use the unitary matrices given in (43), (44) and (50) in sect. III and IV, and will see that the small parameter $s_{13} = \epsilon_e = m_e/(\sqrt{2})/m_\mu \simeq 0.0034$ appears as a suppression factor in FCNCs as well as in some of proton decay modes.

FIG. 2: The effective Majorana mass $\langle m_{ee} \rangle$ as a function of $\sin \phi_\nu$ with $\sin^2 \theta_{12} = 0.3$ and $\Delta m_{21}^2 = 6.9 \times 10^{-5} \text{ eV}^2$. The dashed, solid and dot-dashed lines stand for $\Delta m_{23}^2 = 1.4, 2.3$ and $3.0 \times 10^{-3} \text{ eV}^2$, respectively. The Δm_{21}^2 dependence is very small.

III. THE SUSY FLAVOR PROBLEM

If three generations of a family is put into a one-dimensional and two-dimensional irreps of any dihedral group, then the soft scalar mass matrix for the sfermions has always a diagonal form:

$$\tilde{\mathbf{m}}_{(q,\ell)LL}^2 = m_{\tilde{q},\tilde{\ell}}^2 \begin{pmatrix} a_L^{q,\ell} & 0 & 0 \\ 0 & a_L^{q,\ell} & 0 \\ 0 & 0 & b_L^{q,\ell} \end{pmatrix}, \quad \tilde{\mathbf{m}}_{aRR}^2 = m_{\tilde{q},\tilde{\ell}}^2 \begin{pmatrix} a_R^a & 0 & 0 \\ 0 & a_R^a & 0 \\ 0 & 0 & b_R^a \end{pmatrix} \quad (a = u, d, e), \quad (58)$$

where $m_{\tilde{q},\tilde{\ell}}$ denote the average of the squark and slepton masses, respectively, and $(a_{L(R)}, b_{L(R)})$ are dimensionless free real parameters of $O(1)$. Further, since the trilinear interactions (A terms) are also Q_6 invariant, the left-right mass matrices assume the form

$$(\tilde{\mathbf{m}}_{aLR}^2)_{ij} = A_{ij}^a (\mathbf{m}^a)_{ij} \quad (a = u, d, e), \quad (59)$$

where A_i^a 's are free parameters of dimension one, and the fermion masses $\mathbf{m}$'s are given in (17), (18) and (40). Here we assume that A_i^a 's are in the same order as the gaugino masses. They are real, because we impose CP invariance at the Lagrangian level.

We work in the super CKM basis and calculate

$$\Delta_{LL}^a = U_{aL}^\dagger \tilde{\mathbf{m}}_{(q,\ell)LL}^2 U_{aL} \text{ and } \Delta_{RR(LR)}^a = U_{aR(L)}^\dagger \tilde{\mathbf{m}}_{aRR(LR)}^2 U_{aR} \quad (60)$$

to parameterize FCNCs and CP violations coming from the SSB sector, where the unitary matrices U 's are given in (33), (43) and (44). In doing so, one observes that something interesting happens; a phase alignment. This is because the only source for CP phases comes from VEVs (15). To see the phase alignment, we first observe that the matrices $R_{L,R}$ and the phase rotation matrices $P_{L,R}^{u,d}$, given in (19), (20) and (21), commute with the scalar soft mass matrices $\tilde{\mathbf{m}}_{qLL}^2$ and $\tilde{\mathbf{m}}_{u,dRR}^2$. This implies that $\Delta_{LL,RR}^{u,d}$ are real, where $\Delta_{LL,RR}^e$ is trivially real as we see from (43) and (44). As for the left-right soft mass squared (59), we find that $(P_L^a)^\dagger (R_L^a)^T \tilde{\mathbf{m}}_{aLR}^2 R_R^a P_R^a$ is a real matrix for all $a = u, d, e$. Consequently, no CP violating processes induced by the SSB terms are possible in this model, satisfying the most stringent experimental constraint coming from the EDM of the neutron and the electron [10].

In [10], experimental bounds on the dimensionless quantities

$$\delta_{LL,RR,LR}^a = \Delta_{LL,RR,LR}^a / m_{\tilde{q},\tilde{\ell}}^2 \quad (a = u, d, e), \quad (61)$$

are given. The theoretical values of δ 's for the present model are calculated below, where

$$\Delta a_L^{q,\ell} = a_L^{q,\ell} - b_L^{q,\ell}, \quad \Delta a_R^a = a_R^a - b_R^a, \quad \tilde{A}_i^a = \frac{A_i^a}{m_{\tilde{q},\tilde{\ell}}} \quad (a = u, d, e), \quad (62)$$

are introduced.

Leptonic sector (LL and RR):

$$\begin{aligned} (\delta_{12}^e)_{LL} &= (\delta_{21}^e)_{LL} \simeq 4.9 \times 10^{-3} \Delta a_L^\ell, \\ (\delta_{13}^e)_{LL} &= (\delta_{31}^e)_{LL} \simeq -1.7 \times 10^{-5} \Delta a_L^\ell, \\ (\delta_{23}^e)_{LL} &= (\delta_{32}^e)_{LL} \simeq 8.4 \times 10^{-8} \Delta a_L^\ell, \\ (\delta_{12}^e)_{RR} &= (\delta_{21}^e)_{RR} \simeq 8.4 \times 10^{-8} \Delta a_R^e, \\ (\delta_{13}^e)_{RR} &= (\delta_{31}^e)_{RR} \simeq 5.9 \times 10^{-2} \Delta a_R^e, \\ (\delta_{23}^e)_{RR} &= (\delta_{32}^e)_{RR} \simeq -1.4 \times 10^{-6} \Delta a_R^e. \end{aligned} \quad (63)$$

Leptonic sector (LR):

$$\begin{aligned}
(\delta_{12}^e)_{LR} &\simeq 5.1 \times 10^{-6} \left(\tilde{A}_c^e - \tilde{A}_{b'}^e \right) \left(\frac{100 \text{ GeV}}{m_{\tilde{\ell}}} \right), \\
(\delta_{21}^e)_{LR} &\simeq 2.5 \times 10^{-8} \left(\tilde{A}_c^e - \tilde{A}_{b'}^e \right) \left(\frac{100 \text{ GeV}}{m_{\tilde{\ell}}} \right), \\
(\delta_{13}^e)_{LR} &\simeq 3.1 \times 10^{-7} \left(\tilde{A}_{b'}^e - \tilde{A}_b^e \right) \left(\frac{100 \text{ GeV}}{m_{\tilde{\ell}}} \right), \\
(\delta_{31}^e)_{LR} &\simeq 1.1 \times 10^{-3} \left(\tilde{A}_c^e - \tilde{A}_b^e \right) \left(\frac{100 \text{ GeV}}{m_{\tilde{\ell}}} \right), \\
(\delta_{23}^e)_{LR} &\simeq -1.5 \times 10^{-9} \left(\tilde{A}_{b'}^e - \tilde{A}_b^e \right) \left(\frac{100 \text{ GeV}}{m_{\tilde{\ell}}} \right), \\
(\delta_{32}^e)_{LR} &\simeq -2.5 \times 10^{-8} \left(\tilde{A}_c^e - \tilde{A}_b^e \right) \left(\frac{100 \text{ GeV}}{m_{\tilde{\ell}}} \right).
\end{aligned} \tag{64}$$

Up quark sector (LL and RR):

$$\begin{aligned}
(\delta_{12}^u)_{LL} &= (\delta_{21}^u)_{LL} \simeq 1.0 \times 10^{-4} \Delta a_L^q, \\
(\delta_{13}^u)_{LL} &= (\delta_{31}^u)_{LL} \simeq 2.3 \times 10^{-3} \Delta a_L^q, \\
(\delta_{23}^u)_{LL} &= (\delta_{32}^u)_{LL} \simeq -4.4 \times 10^{-2} \Delta a_L^q, \\
(\delta_{12}^u)_{RR} &= (\delta_{21}^u)_{RR} \simeq -4.5 \times 10^{-4} \Delta a_R^u, \\
(\delta_{13}^u)_{RR} &= (\delta_{31}^u)_{RR} \simeq 4.8 \times 10^{-3} \Delta a_R^u, \\
(\delta_{23}^u)_{RR} &= (\delta_{32}^u)_{RR} \simeq 9.3 \times 10^{-2} \Delta a_R^u.
\end{aligned} \tag{65}$$

Up quark sector (LR):

$$\begin{aligned}
(\delta_{11}^u)_{LR} &\simeq 10^{-6} \left[3.8 \left(\tilde{A}_a^u - \tilde{A}_b^u - \tilde{A}_{b'}^u + 2\tilde{A}_c^u \right) \right] \left(\frac{500 \text{ GeV}}{m_{\tilde{q}}} \right), \\
(\delta_{22}^u)_{LR} &\simeq 10^{-3} \left[-1.4 \left(\tilde{A}_a^u - \tilde{A}_b^u - \tilde{A}_{b'}^u \right) + 7.7 \times 10^{-3} \tilde{A}_c^u \right] \left(\frac{500 \text{ GeV}}{m_{\tilde{q}}} \right), \\
(\delta_{33}^u)_{LR} &\simeq \left[0.35 \tilde{A}_a^u + 6.8 \times 10^{-4} \tilde{A}_b^u + 3.0 \times 10^{-3} \tilde{A}_{b'}^u + 1.7 \times 10^{-10} \tilde{A}_c^u \right] \left(\frac{500 \text{ GeV}}{m_{\tilde{q}}} \right), \\
(\delta_{12}^u)_{LR} &\simeq -(\delta_{21}^u)_{LR} \simeq 7.4 \times 10^{-5} \left(\tilde{A}_a^u - \tilde{A}_b^u - \tilde{A}_{b'}^u + \tilde{A}_c^u \right) \left(\frac{500 \text{ GeV}}{m_{\tilde{q}}} \right), \\
(\delta_{13}^u)_{LR} &\simeq 10^{-4} \left[-7.9 \left(\tilde{A}_a^u - \tilde{A}_b^u \right) - 7.0 \times 10^{-2} \left(\tilde{A}_{b'}^u - \tilde{A}_c^u \right) \right] \left(\frac{500 \text{ GeV}}{m_{\tilde{q}}} \right), \\
(\delta_{31}^u)_{LR} &\simeq 10^{-3} \left[-1.7 \left(\tilde{A}_a^u - \tilde{A}_{b'}^u \right) - 3.3 \times 10^{-3} \left(\tilde{A}_b^u - \tilde{A}_c^u \right) \right] \left(\frac{500 \text{ GeV}}{m_{\tilde{q}}} \right), \\
(\delta_{23}^u)_{LR} &\simeq 10^{-2} \left[1.5 \left(\tilde{A}_a^u - \tilde{A}_b^u \right) + 1.3 \times 10^{-2} \tilde{A}_{b'}^u + 3.6 \times 10^{-5} \tilde{A}_c^u \right] \left(\frac{500 \text{ GeV}}{m_{\tilde{q}}} \right), \\
(\delta_{32}^u)_{LR} &\simeq 10^{-2} \left[-3.2 \left(\tilde{A}_a^u - \tilde{A}_{b'}^u \right) - 6.4 \times 10^{-3} \tilde{A}_b^u - 1.7 \times 10^{-5} \tilde{A}_c^u \right] \left(\frac{500 \text{ GeV}}{m_{\tilde{q}}} \right).
\end{aligned} \tag{66}$$

Down quark sector (LL and RR):

$$\begin{aligned}
(\delta_{12}^d)_{LL} &= (\delta_{21}^d)_{LL} \simeq 1.2 \times 10^{-4} \Delta a_L^q, \\

TABLE III: Experimental bounds on δ 's and the theoretical values in Q_6 model, where the parameter $\tilde{m}_{\tilde{\ell}}$ denote $m_{\tilde{\ell}}/100$ GeV and $\Delta a_{L,R}$ and $\tilde{A}$ are given in (62).

constraints, the SSB parameters Δa_R^d , Δa_L^ℓ , $\tilde{A}_{b'}^e$ and $\tilde{A}_c^e$ of the present Q_6 model should satisfy

$$\Delta a_R^d < 10^{-1}, \quad \Delta a_L^\ell < 10^{-2}, \quad \tilde{A}_{b'}^e - \tilde{A}_c^e < 10^{-1}, \quad (69)$$

while the other SSB parameters are allowed to be of $O(1)$. So, one can fairly say that Q_6 symmetry can soften the SUSY flavor problem. Note also that the degree of degeneracy of the left-handed squark masses Δa_L^q does not need to be very accurate. We find that because of the constraint on Δa_R^d given in (69), $\Delta a_L^q < 10^{+1}$ is sufficient to satisfy all the constraints. This has an important consequence for proton decay as we will see in the next section.

IV. PROTON DECAY

In this section we consider proton decay, which is a process reflecting the flavor structure of a model.

A. Q_6 invariant baryon and lepton number violating operators

In supersymmetric models, the baryon and/or lepton number violating operators of lower dimensions are [27]:

1. dimension-four R parity violating operators, and
2. dimension-five baryon and lepton number violating operators.

Both operators are controlled by the flavor structure of a model. As for the dimension-four R parity violating operators, Q_6 flavor symmetry in the model considered in the previous sections allows only lepton number violating operators:

$$\begin{aligned}
LLE^c &: \lambda_{113}L_IL_IE_3^c + \lambda_{311}L_3L_IE_I^c + \lambda_{333}L_3L_3E_3^c + \lambda f_{IJK}L_IL_JE_K^c, \\
LQD^c &: \lambda'_{132}L_I(i\sigma^2)_{IJ}Q_3D_J^c + \lambda'_{123}L_I(\sigma^1)_{IJ}Q_JD_3^c, \\
H^dNH^u &: \tilde{\lambda}_{312}H_3^dN_IH_I^u + \tilde{\lambda}_{333}H_3^dN_3H_3^u + \tilde{\lambda}f_{IJK}H_I^dN_JH_K^u, \\
NNN &: \tilde{\lambda}'f_{IJK}N_IN_JN_K,
\end{aligned} \tag{70}$$

and those in which L_I is replaced by H_I^d . Note that the baryon number violating operator $U^cD^cD^c$ is forbidden by Q_6 symmetry. Therefore, the dimension-four operators in the present model can not mediate proton decay.

We next look at dimension-five operators. The baryon number violating dimension-five operators (which are allowed by R parity and $B - L$ symmetry) can be written as [27, 28, 52, 53]

$$W_5 = \frac{1}{M} \sum_{i,j,k,l=1\sim 3} \left[\frac{1}{2} C_L^{ijkl} Q_i Q_j Q_k L_l + C_R^{ijkl} U_i^c E_j^c U_k^c D_l^c \right], \tag{71}$$

where the first and the second term is called the LLLL and RRRR operator, respectively. In grand unified theories(GUTs), effective dimension-five operators can be generated by integrating out colored Higgs multiplets [27, 28], and therefore the size of the coefficients of the operators strongly depends the Yukawa matrices. For the minimal SUSY $SU(5)$ GUT [53], one obtains

$$M = M_{H_C}, \quad C_L^{ijkl} = C_R^{ijkl} = Y_U^{ij} Y_D^{kl} \quad \text{at } M_{GUT}, \tag{72}$$

where M_{H_C} is the colored Higgs mass of order of the GUT scale, and Y_U, Y_D are Yukawa coupling matrices appearing in the superpotential

$$W_Y = \frac{1}{4} Y_U^{ij} \mathbf{10}^i \mathbf{10}^j H + \sqrt{2} Y_D^{ij} \mathbf{10}^i \bar{\mathbf{5}}^j \bar{H}. \tag{73}$$

Unfortunately, the minimal SUSY $SU(5)$ GUT should be excluded by the decay mode $p \rightarrow K^+ \bar{\nu}$ if the gauge coupling unification should be strictly satisfied [29].

If we do not assume any GUTs, the baryon number violating operators could be generated by some unknown Planck scale physics. In this case, the mass parameter M in (71) is given by

$$M = M_{PL} = 2 \times 10^{18} \text{GeV}, \tag{74}$$

while the coefficients $C_{L,R}^{ijkl}$ remain undetermined. So, the operators are supplied with a suppression factor $1/M_{PL}$ which should be compared with $1/M_{HC} \simeq 1/10^{16} \text{ GeV}^{-1}$ in the GUT case. However, this suppression is not sufficient to keep the proton stable, unless that the coefficients C 's are smaller than $\sim O(10^{-7})$. An efficient tool to suppress or to forbid proton decay is symmetry. Many authors [23, 30, 54] have proposed a model in which both the gross structure of the baryon and lepton number violating operators and the structure of the Yukawa couplings are fixed by a single flavor symmetry and its breaking. If this is realized, the flavor symmetry can be tested by proton decay, too. In the models of [23, 30, 54], a certain set of flavon fields is needed to form invariants, and the flavor symmetry is assumed to be broken at a superhigh energy scale. In contrast to these models, Q_6 flavor symmetry is broken (spontaneously and at most softly) only at a low energy scale which is comparable with the SUSY breaking scale. So, it is natural to assume that Q_6 flavor symmetry is intact at the Planck scale, too; we do not have to introduce flavon fields. Moreover, Q_6 is nonabelian, which can indeed reduce the number of independent coefficients drastically, as we will see now. We find that the relevant superpotential containing the baryon number violating Q_6 invariant dimension-five operators generated at the Planck scale can be written as

$$W_5^{Q_6} = \frac{1}{M_{PL}} \sum_{I,J=1,2} \left[C_L Q_I Q_I Q_3 L_3 + C_R^{(1)} E_I^c (i\sigma^2)_{IJ} U_J^c U_3^c D_3^c + C_R^{(2)} E_I^c (i\sigma^2)_{IJ} U_1^c U_2^c D_J^c \right] \quad (75)$$

where the superfields in (75) are in the flavor eigenstates. To obtain Eq.(75), we have not assumed any symmetries such as R-parity and $B - L$ except for Q_6 symmetry, where the Q_6 assignment is given in Table I.

B. Gross structure of the dimension-five operators and the lowest order approximation

As we can see from (75), Q_6 allows only three independent coefficients, $C_L, C_R^{(1)}$ and $C_R^{(2)}$. We will see moreover that the first term, the LLLL operator, gives the most dominant contribution to proton decay, while the RRRR operators can be neglected in the lowest order approximation. Consequently, the relative size of all the partial decay rates is fixed in this approximation, once the SSB sector is fixed. To begin with, we recall two basic facts:

1. Since the operators in the first two terms in $W_5^{Q_6}$ contain quark fields of the third generation in the flavor eigenstate, small mixing parameters appear when fields are rewritten in terms of the mass eigenstates, that is,

$$\Phi_3^f = V_{3I} \Phi_I^m, \quad I = 1, 2, \quad (76)$$

where the subscripts f and m denote the flavor and mass eigenstates, respectively. The mixing parameters V_{3I} will be multiplied with the coefficients C 's in the decay

amplitudes, so that the condition on C 's can be relaxed if V_{3I} are small (see (36)~(39)). Note that within the framework of the MSSM, there is no such suppression.

2. In most of models, the universality of the SSB parameters at the GUT or Planck scale is assumed to suppress the SUSY contributions to FCNCs. This assumption has an important consequence that the gluino contributions to proton decay are negligibly small if all the squark masses are degenerate [55]. (In Fig. 3. we show a gaugino dressing diagram which contributes to an effective four-fermion operator.) However, in our case, we do not assume the universality. We have seen in the previous section that the degeneracy of the squark masses of the first two generations is almost exact due to Q_6 symmetry. Moreover, to suppress the SUSY contributions to FCNCs the degeneracy of the first two and third generations needs not to be accurate (see Eq. (69) and the discussions below). This means that the gluino dressing diagrams may not be negligible [56] in our case; we will have to investigate it.

We now argue that the first term, the LLLL operator, is the most dominant one. It is known that for the RRRR operators, the dominant contributions come from the gluino dressing diagrams. From the superpotential (75), we first observe that the second term in (75), the first RRRR operator, contains two quark fields of the third generation, implying that two small mixing parameters will be multiplied when going to the mass eigenstates. Further, the third term, the second RRRR term, contains only quark fields of the first two generation. That is, the gluino dressing contributions vanish because the squark masses of the first two generations are almost degenerate thanks to Q_6 symmetry. Thus, the LLLL operator is the only one which should be considered in the lowest order approximation, as we will do it in the following discussions.

Note that the LLLL operator contains two third generation fields Q_3 and L_3 , but the (3,1) element of the mixing matrix U_{eL} (see (43)) is equal to one, so that it does not act as a suppression factor. The dominant diagrams for the LLLL operator are those with gluino dressing. The zino and photino dressing diagrams have the same structure as the gluino ones, but they are negligibly small because the corresponding gauge couplings are small. So we ignore them in our calculations. We have calculated the higgsino dressing contributions and found that they can be neglected, too, if $\tan\beta < 10$. So we assume this to simplify our calculations. We may further approximate that the squark masses are diagonal in the super CKM basis. To see this, we recall that the squark mass squared in the super CKM basis can be written as

$$\mathbf{m}_a^2 = (\mathbf{m}_{f_a})^2 + \begin{pmatrix} \Delta_{LL}^a & \Delta_{LR}^{a*} \\ \Delta_{LR}^{aT} & \Delta_{RR}^{aT} \end{pmatrix}, \quad a = u, d, e \quad (77)$$

where $\mathbf{m}_{f_a}$ is the diagonal fermion mass matrix of the flavor a , and Δ 's are given in (60). As we can see from (64), (66) and (69), the nondiagonal elements are sufficiently small.

FIG. 3: One-loop diagrams contributing to the effective four-fermi Lagrangian (78). We consider only gluino ($\tilde{g}$) and wino ($\tilde{w}$) dressings in the lowest order approximation.

The effective four-fermi Lagrangian $\mathcal{L}_{\text{eff}}$ can be obtained from the diagrams shown in Fig. 3, where as argued we consider only gluino and wino dressings. We find ⁵

$$\mathcal{L}_{\text{eff}} = \frac{1}{(4\pi)^2 M_{PL}} \left[\sum_{\substack{M=d,s \\ l=e,\mu}} C_{LL}(udue)^{1M1l} (ud^M)(ue^l) + \sum_{\substack{M,N=d,s \\ l=e,\mu,\tau}} C_{LL}(udd\nu)^{1MNI} (ud^M)(d^N\nu^l) \right] \quad (78)$$

$$\begin{aligned} C_{LL}(udue)^{1M1l} &= \tilde{C}_{LL}^{\tilde{g}}(udue)^{1M1l} + \tilde{C}_{LL}^{\tilde{w}}(udue)^{1M1l}, \\ C_{LL}(udd\nu)^{1MNI} &= \tilde{C}_{LL}^{\tilde{g}}(udd\nu)^{1MNI} + \tilde{C}_{LL}^{\tilde{w}}(udd\nu)^{1MNI}, \end{aligned} \quad (79)$$

where $\tilde{C}^{\tilde{g}}$ and $\tilde{C}^{\tilde{w}}$ stand for the contributions coming from the gluino and wino dressing diagrams, respectively. These are explicitly calculated to be

$$\begin{aligned} \tilde{C}_{LL}^{\tilde{g}}(udd\nu)^{1MNI} &= 4\pi \frac{4\alpha_3}{3} \sum_{I=1,2} U_{uL}^{I1} U_{dL}^{IM} U_{dL}^{3N} U_{eL}^{3l} (F^{\tilde{g}}(a_L^q, b_L^q) - F^{\tilde{g}}(a_L^q, a_L^q)), \\ \tilde{C}_{LL}^{\tilde{w}}(udd\nu)^{1MNI} &= 4\pi \alpha_2 \sum_{I=1,2} [U_{uL}^{I1} U_{dL}^{IM} U_{dL}^{3N} U_{eL}^{3l} (F^{\tilde{w}}(a_L^q, a_L^q) + F^{\tilde{w}}(b_L^q, b_L^\ell)) \\ &\quad - U_{uL}^{31} U_{dL}^{IM} U_{dL}^{IN} U_{eL}^{3l} (F^{\tilde{w}}(a_L^q, b_L^q) + F^{\tilde{w}}(a_L^q, b_L^\ell))] , \end{aligned} \quad (80)$$

$$\begin{aligned} \tilde{C}_{LL}^{\tilde{g}}(udue)^{1M1l} &= -4\pi \frac{4\alpha_3}{3} \sum_{I=1,2} U_{uL}^{I1} U_{dL}^{IM} U_{uL}^{31} U_{eL}^{3l} (F^{\tilde{g}}(a_L^q, b_L^q) - F^{\tilde{g}}(a_L^q, a_L^q)), \\ \tilde{C}_{LL}^{\tilde{w}}(udue)^{1M1l} &= -4\pi \alpha_2 \sum_{I=1,2} [U_{uL}^{I1} U_{dL}^{IM} U_{uL}^{31} U_{eL}^{3l} (F^{\tilde{w}}(a_L^q, a_L^q) + F^{\tilde{w}}(b_L^q, b_L^\ell)) \\ &\quad - U_{uL}^{I1} U_{dL}^{3M} U_{uL}^{I1} U_{eL}^{3l} (F^{\tilde{w}}(a_L^q, b_L^q) + F^{\tilde{w}}(a_L^q, b_L^\ell))] , \end{aligned} \quad (81)$$

⁵ We use the notation of [57, 58].

where the loop functions are defined as [57, 58]

$$F^{\tilde{g}}(a_L^q, b_L^q) = \frac{1}{m_{\tilde{g}}} \frac{1}{x_{g1} - x_{g3}} \left[\frac{x_{g1} \ln x_{g1}}{x_{g1} - 1} - \frac{x_{g3} \ln x_{g3}}{x_{g3} - 1} \right],$$

$$F^{\tilde{w}}(a_L^q, b_L^\ell) = \frac{1}{m_{\tilde{w}}} \frac{1}{x_{w1} - y_{w3}} \left[\frac{x_{w1} \ln x_{w1}}{x_{w1} - 1} - \frac{y_{w3} \ln y_{w3}}{y_{w3} - 1} \right],$$

with

$$x_{g,w1} = \frac{m_{\tilde{q}}^2}{m_{\tilde{g},\tilde{w}}^2} a_L^q, \quad x_{g,w3} = \frac{m_{\tilde{q}}^2}{m_{\tilde{g},\tilde{w}}^2} b_L^q, \quad y_{w3} = \frac{m_\ell^2}{m_{\tilde{w}}^2} b_L^\ell. \quad (82)$$

We also use $\Delta_Q \equiv \Delta a_L^q = a_L^q - b_L^q$ (which is first introduced in (62)) and

$$r_g = \frac{m_{\tilde{g}}^2}{m_{\tilde{g}}^2}. \quad (83)$$

Then we calculate the decay amplitudes as a function of x_{g3} for given values of $r_g \Delta_Q$ and y_{w3} , while for simplicity we assume the GUT relation between the wino and gluino mass ⁶

$$m_{\tilde{w}} = 0.27 m_{\tilde{g}}. \quad (84)$$

The unitary matrices $U_{(u,d,e)L}$ in C_{LL} are explicitly given in (36), (37) and (43), where the individual phases $\theta^{u,d}$ and $\theta_3^{u,d}$ in the quark sector are not fixed (see(26)). However, it is found from (36) and (37) that the phase dependence of the combinations appearing in C_{LL} , that is, $U_{uL}^{I1} U_{dL}^{I(1,2)}$ and $U_{(u,d)L}^{I1} U_{(u,d)L}^{I1}$, is small, and moreover the absolute size of the suppression factor $U_{(u,d)L}^{3I}$ is independent of the phases. Therefore, in the following calculations we choose

$$\theta^u = \theta_3^u = 0, \quad \theta_3^d - \theta^d = -1.25 \quad (85)$$

without significantly changing the results.

C. Gluino versus wino contributions

Before we calculate the decay amplitudes, we investigate the relative size of the gluino and wino contributions. As pointed out, to suppress the SUSY contributions to FCNCs in Q_6 model the degeneracy of the first two and third generations needs not to be exact. In fact, as we can see from Table III and Eq. (69), $\Delta_Q \leq 10$ is sufficient. ($\Delta_Q \equiv \Delta a_L^q$ defined in (62) expresses the degree of the degeneracy of the squark masses.) If this is a case, the cancellation of the gluino contributions is no longer perfect [56], so that they may dominate over the wino ones. In Figs. 4-5, we present the results on the ratio $C^{\tilde{g}}/C^{\tilde{w}}$ as a function of x_{g3} for $r_g \Delta_Q = (10, 1, 0.1, 0.01)$ and $y_{w3} = 10$ (right), 1 (left). Figs. 4 show the results

⁶ If we change the GUT relation (84), the results below can change only slightly.

on $C(udd\nu)$'s which control the size of the anti-neutrino modes, while Figs. 5 are those on $C(udue)$'s for the decay amplitudes into a charged lepton. We can see furthermore that (except for $C(udue)^{121l}$ shown in the last two figures of Figs. 5) the gluino contributions can become of the same order as the wino ones for $x_{g_3} \sim O(1)$ if $r_g\Delta_Q \gtrsim 1$. We can also see that the smaller the value of $r_g\Delta_Q$ is, the smaller are the gluino contributions, as it should be.

If the degeneracy of the squark masses is assumed, the gluino contributions vanish, and the wino contributions are then the dominant ones. This is assumed in most of the previous investigations on proton decay. Let us call the wino contribution under the assumption of the degeneracy (that is, $\Delta_Q = 0$) $C_{LL}(\cdots)_{MSSM}^{\tilde{w}}$, and compare it with $C_{LL}(\cdots)_{Q_6}^{\tilde{g}}$ for which Δ_Q may be different from zero. Since it will turn out that the decay mode $p \rightarrow K^+\bar{\nu}$ has the largest rate, we restrict ourselves to $C_{LL}(udd\nu)^{112l}$ (which gives the largest contribution to the decay mode). Fig. 6 shows the ratio $C_{LL}^{\tilde{g}}(udd\nu)_{Q_6}^{112l}/C_{LL}^{\tilde{w}}(udd\nu)_{MSSM}^{112l}$ as a function of x_{g_3} for $r_g\Delta_Q = 10$ and $y_{w_3} = 1, 10$. We see from the figure that the gluino contribution in Q_6 model is smaller than the wino ones of the MSSM, although the $SU(3)_C$ gauge coupling is larger than that the $SU(2)_L$ gauge coupling. This is due to the fact that the LLLL operator in (75) contains one Q_3 which requires a small mixing parameter to appear when expressed in terms of the mass eigenstates of the first two generations.

D. Partial decay widths and their relative size

Here we calculate the partial decay widths of the proton. The partial decay widths for the decay mode $p \rightarrow M\ell$, $\Gamma(p \rightarrow M\ell)$, can be written as [58]

$$\Gamma(p \rightarrow M\ell) = \left(\frac{\mathcal{A}\beta_p}{(4\pi)^2 M_{PL}} \right)^2 \frac{(m_P^2 - m_M^2)^2}{32\pi m_P^3 f_\pi^2} |Amp(p \rightarrow M\ell)|^2, \quad (86)$$

with

$$Amp(p \rightarrow K^+\bar{\nu}) = \kappa_6 C_{LL}(udd\nu)^{121l} + \kappa_2 C_{LL}(udd\nu)^{112l} \quad (87)$$

$$Amp(p \rightarrow \pi^+\bar{\nu}) = \sqrt{2}\kappa_5 C_{LL}(udd\nu)^{111l}, \quad (88)$$

$$Amp(p \rightarrow K^0 e_l^+) = \kappa_1 C_{LL}(udue)^{121l}, \quad (89)$$

$$Amp(p \rightarrow \pi^0 e_l^+) = \kappa_5 C_{LL}(udue)^{111l}, \quad (90)$$

where κ 's are defined by [58]

$$\begin{aligned} \kappa_1 &= 1 + \frac{m_P}{m_B}(F - D) = 0.70, & \kappa_2 &= 1 + \frac{m_P}{3m_B}(3F + D) = 1.6, \\ \kappa_3 &= 1 + \frac{m_P}{m_B}(F + D) = 2.0, & \kappa_4 &= 2 + \frac{2m_P}{m_B}F = 2.7, \\ \kappa_5 &= \frac{1}{\sqrt{2}}(1 + F + D) = 1.6, & \kappa_6 &= \frac{2m_P}{3m_B}D = 0.4, \end{aligned} \quad (91)$$

FIG. 4: The ratio $C^{\tilde{g}}(udd\nu)/C^{\tilde{w}}(udd\nu)$ is plotted as a function of x_{g3} for $r_g\Delta Q = (10, 1, 0.1, 0.01)$, which expresses the degree of the degeneracy of the squark masses, where x_{g3} is defined in (82). $C^{\tilde{g}}$'s stand for the gluino contributions and $C^{\tilde{w}}$'s for the wino ones, respectively. The figures in the left column correspond to $y_{w3} = 1$, and those in the right column to $y_{w3} = 10$. The corresponding amplitudes are responsible for the anti-neutrino modes.

and

$$\begin{aligned}
 D &= 0.81, \quad F = 0.44, \quad \beta_p = 0.003 \text{ GeV}^3, \quad f_\pi = 131 \text{ MeV}, \\
 m_P &= 938 \text{ MeV}, \quad m_B = 1150 \text{ MeV}, \quad m_K = 495 \text{ MeV}, \quad m_\pi = 140 \text{ MeV}.
 \end{aligned} \tag{92}$$

FIG. 5: The same as Fig. 4 for the charged lepton modes.

FIG. 6: Ratio of $C_{LL}^{\tilde{g}}(u d d \nu)^{112l}_{Q_6}$ to $C_{LL}^{\tilde{w}}(u d d \nu)^{112l}_{MSSM}$ as a function of x_{g3} , where $r_g \Delta Q = 10$ is assumed for $C_{LL}^{\tilde{g}}(u d d \nu)^{112l}_{Q_6}$, where x_{g3} is defined in (82). $C_{LL}(u d d \nu)^{112l}$ is the largest coefficient for $p \rightarrow K^+ \bar{\nu}$, and the degeneracy of the squark masses ($\Delta_Q = 0$) is assumed for $C_{LL}^{\tilde{w}}(u d d \nu)^{112l}_{MSSM}$.

Here, D , F stand for the coupling constants for the interaction between baryons and mesons, β_p for the hadronic matrix element, f_π for the pion decay constant, m_P for the proton mass, m_B for the averaged baryon mass, and m_K and m_π for the Kaon and pion mass, respectively. Further, $\mathcal{A}$ is the renormalization group(RG) enhancement factor for the coefficient C_L

[28, 53], which in our case becomes

$$\mathcal{A} = 10.5 \quad (\text{for the MSSM}), \quad 12 \quad (\text{for } Q_6 \text{ model}). \quad (93)$$

(Since Q_6 model contains four more Higgs doublets than in the case of the MSSM, the enhancement factor is slightly larger.)

As the first task, we would like to compare the decay rates in the MSSM and Q_6 model. By the MSSM decay rates we mean the decay rates which are obtained from the LLLL operators under the assumption of the degenerate squark masses (no gluino dressing). We also assume that all the coefficients of the operators are equal to the single constant C_L^{MSSM} , and that all the fields appearing in the operators are in the mass eigenstates (no mixing matrix). In Figs. 7, we plot for each decay mode, the experimental bound (thick solid line), the partial lifetime calculated in Q_6 model (solid line) and that in the MSSM (dotted line), where we assume

$$C_L = C_L^{MSSM} = 1, \quad m_{\tilde{q}} = 1 \text{ TeV}. \quad (94)$$

The lifetime in Q_6 model is calculated from the sum of the gluino and wino contributions for $r_g \Delta_Q = 0.01, 0.1, 1, 10$, which corresponds to four solid lines. We first see from the figures that if $r_g \Delta_Q$ varies from 0.01 to 10, a change of the life time about an order of magnitude can appear. We also see that the decay rates in Q_6 model is much more suppressed than those in the MSSM. Quantitatively, we find that the experimental bounds can be satisfied if the coefficient for the LLLL operator satisfies

$$C_L < 10^{-(4 \sim 5)}, \quad (95)$$

while $C_L^{MSSM} < 10^{-(6 \sim 7)}$ should be satisfied for the case of the MSSM. That is, Q_6 flavor symmetry can suppress proton decay by four orders of magnitude (which can be also seen from the figures).

Next we would like to compare our results with those obtained in the minimal SUSY $SU(5)$ GUT. In our lowest order approximation, only C_L is an independent coefficient, implying that the ratio of partial decay widths is independent of C_L . That is, in Q_6 model, the relative size of the partial decay rates is fixed (once the SSB sector is fixed). First we recall the case of the minimal SUSY $SU(5)$ GUT [30, 53]. The superpotential for the baryon number violating effective dimension-five operators in this case is given by

$$W_5^{SU(5)} = \frac{1}{2M_{HC}} [y_u y_{dl} (V^*)_{2l} (Q_1 Q_1) (Q_2 L_l) + y_c y_{dl} (V^*)_{1l} (Q_2 Q_2) (Q_1 L_l)] \quad (96)$$

in the approximation that the third generation is dropped, where $y_{u,c}, y_{dl}$ are the diagonal Yukawa couplings of the corresponding quarks, $l = 1, 2$ is generation index (i.e., $d1 = d$ and $d2 = s$), and V is the CKM matrix. In writing (96), a nontrivial assumption is made; the up quark Yukawa matrix is diagonal over the whole range of energies. Therefore, the

FIG. 7: Partial lifetime of the proton for each decay mode as a function of x_{g3} with $C_L = C_L^{MSSM} = 1$, $m_{\tilde{g}} = 1$ TeV. The experimental bound (thick solid line), the partial lifetime calculated in Q_6 model (solid line) and that in the MSSM (dotted line) are plotted. The lifetime in Q_6 model is calculated from the sum of the gluino and wino contributions for $r_g \Delta_Q = 0.01, 0.1, 1, 10$, which corresponds to four solid lines.

superpotential (96) is not a unique prediction of the the model. Under the assumption of the degeneracy of the squark masses, only the wino dressing diagrams contribute to the decay, and one finds [30, 53]

$$\Gamma(p \rightarrow K^+ \bar{\nu}) = \gamma (m_P^2 - m_K^2)^2 |y_c y_s \sin^2 \theta_C \kappa_3|^2, \quad (97)$$

$$\Gamma(p \rightarrow \pi^+ \bar{\nu}) = \gamma (m_P^2 - m_\pi^2)^2 |2y_c y_s \sin^2 \theta_C \tan \theta_C \sqrt{2} \kappa_5|^2, \quad (98)$$

$$\Gamma(p \rightarrow K^0 e_l^+) = \gamma (m_P^2 - m_K^2)^2 |y_u y_d (V^*)_{2l} \cos \theta_C \kappa_1|^2, \quad (99)$$

$$\Gamma(p \rightarrow \pi^0 e_l^+) = \gamma (m_P^2 - m_\pi^2)^2 |y_u y_d (V^*)_{2l} \sin \theta_C \kappa_5|^2, \quad (100)$$

where we have dropped the corresponding loop functions (82), and the common factor γ is given by

$$\gamma = \left(\frac{\mathcal{A} \beta_p \alpha_2 \cos \theta_C}{\pi M_{H_C}} \right)^2 \frac{1}{32 \pi m_P^3 f_\pi^2}. \quad (101)$$

FIG. 8: Ratio of partial decay rates for each decay mode with $r_g \Delta Q = (10, 1, 0.1, 0.01)$. Figures in the left column are for $y_{w3} = 1$, and the right column for $y_{w3} = 10$.

From these partial decay widths, we obtain the relative decay widths in the minimal $SU(5)$ GUT [30, 53]:

$$\frac{B(p \rightarrow K^+ \bar{\nu})}{B(p \rightarrow \pi^+ \bar{\nu})} = \frac{(m_P^2 - m_K^2)^2}{(m_P^2 - m_\pi^2)^2} \left(\frac{\kappa_3}{2\sqrt{2}\kappa_5 \tan \theta_C} \right)^2 \simeq 2, \quad (102)$$

$$\frac{B(p \rightarrow K^0 e_l^+)}{B(p \rightarrow \pi^0 e_l^+)} = \frac{(m_P^2 - m_K^2)^2}{(m_P^2 - m_\pi^2)^2} \left(\frac{\kappa_1 \cos \theta_C}{\kappa_5 \sin \theta_C} \right)^2 \simeq 2, \quad (103)$$

$$\frac{B(p \rightarrow K^0 \mu^+)}{B(p \rightarrow K^+ \bar{\nu})} = \left(\frac{y_u \kappa_1 \cos \theta_C}{y_c \kappa_3 \sin^2 \theta_C} \right)^2 \simeq 6 \times 10^{-4}, \quad (104)$$

$$\frac{B(p \rightarrow \pi^0 \mu^+)}{B(p \rightarrow \pi^+ \bar{\nu})} = \left(\frac{y_u \cos^2 \theta_C}{2\sqrt{2}y_c \sin^2 \theta_C} \right)^2 \simeq 3 \times 10^{-4}. \quad (105)$$

FIG. 9: Ratio of partial decay rates for each decay mode with $r_g \Delta_Q = (10, 1, 0.1, 0.01)$. Figures in the left column are for $y_{w3} = 1$, and the right column for $y_{w3} = 10$.

The corresponding results for Q_6 model are found to be

$$\frac{B(p \rightarrow K^+ \bar{\nu})}{B(p \rightarrow \pi^+ \bar{\nu})} = \frac{(m_P^2 - m_K^2)^2}{(m_P^2 - m_\pi^2)^2} \left(\frac{\kappa_2 U_{dL}^{32}}{\sqrt{2} \kappa_5 U_{dL}^{31}} \right)^2 \simeq \begin{cases} 1.25 \\ 1 \end{cases}, \quad (106)$$

$$\frac{B(p \rightarrow K^0 e_l^+)}{B(p \rightarrow \pi^0 e_l^+)} = \frac{(m_P^2 - m_K^2)^2}{(m_P^2 - m_\pi^2)^2} \left\{ \begin{array}{l} \left(\frac{\kappa_1 U_{dL}^{32}}{\kappa_5 U_{dL}^{31}} \right)^2 \\ \left(\frac{\kappa_1 U_{uL}^{31} \sin \theta_C}{\kappa_5 U_{uL}^{31}} \right)^2 \end{array} \right\} \simeq \begin{cases} 0.5 \\ 5 \times 10^{-3} \end{cases}, \quad (107)$$

$$\frac{B(p \rightarrow K^0 e_l^+)}{B(p \rightarrow K^+ \bar{\nu})} = \left(\frac{\kappa_1}{\kappa_2} \right)^2 |U_{eL}^{3l}|^2 \left\{ \begin{array}{l} 1 \\ \left(\frac{U_{uL}^{31} \sin \theta_C}{U_{dL}^{32}} \right)^2 \end{array} \right\} \simeq |U_{eL}^{3l}|^2 \left\{ \begin{array}{l} 0.2 \\ 2.4 \times 10^{-4} \end{array} \right\}, \quad (108)$$

$$\frac{B(p \rightarrow \pi^0 e_l^+)}{B(p \rightarrow \pi^+ \bar{\nu})} = \frac{1}{2} |U_{eL}^{3l}|^2 \left\{ \begin{array}{l} 1 \\ \left(\frac{U_{uL}^{31}}{U_{dL}^{31}} \right)^2 \end{array} \right\} \simeq |U_{eL}^{3l}|^2 \left\{ \begin{array}{l} 0.5 \\ 5.1 \times 10^{-2} \end{array} \right\}, \quad (109)$$

where as in the case of the minimal SUSY GUT we have suppressed the loop functions. The upper (lower) numbers on the right hand side correspond to the wino (gluino) contributions. Note that in contrast to the case of the minimal SUSY GUT the mixing parameters explicitly appear, reflecting the flavor structure of the present Q_6 model. The most remarkable difference is the charged lepton modes. As we see from (108) and (109), they are proportional

to $|U_{eL}^{3l}|^2$, where the unitary matrix U_{eL} (which rotates the left-handed charged leptons) is explicitly given in (43). We find

$$\begin{aligned} \frac{B(p \rightarrow K^0 \mu^+)}{B(p \rightarrow K^0 e^+)} &= \frac{B(p \rightarrow \pi^0 \mu^+)}{B(p \rightarrow \pi^0 e^+)} = \frac{|U_{eL}^{32}|^2}{|U_{eL}^{31}|^2} \\ &= \left(\frac{m_e}{m_\mu} \right)^2 \simeq 2.37 \times 10^{-5}. \end{aligned} \quad (110)$$

The same ratio in the case of the minimal SUSY GUT becomes $B(p \rightarrow K^0 \mu^+) \simeq 10^3 \times B(p \rightarrow K^0 e^+)$ if we use the superpotential (96). In Figs. 8 and 9 we plot four different combinations of ratios as a function of x_{g3} for various values of $r_g \Delta_Q$ in Q_6 model. The figures on the left (right) side correspond to $y_{w3} = 1(10)$. From the figures, we find the hierarchical structure of the decay modes:

$$B(p \rightarrow K^0 e^+) < B(p \rightarrow \pi^0 e^+) < B(p \rightarrow \pi^+ \bar{\nu}) < B(p \rightarrow K^+ \bar{\nu}). \quad (111)$$

In the case of the minimal SUSY GUT we obtain instead

$$B(p \rightarrow \pi^0 e^+) < B(p \rightarrow K^0 e^+) \ll B(p \rightarrow \pi^+ \bar{\nu}) < B(p \rightarrow K^+ \bar{\nu}). \quad (112)$$

Note, however, that although $B(p \rightarrow \pi^0 e^+) < B(p \rightarrow K^+ \bar{\nu})$, they are basically in the same order in the Q_6 model. That is, the Q_6 model predicts that once the decay mode $K^+ \bar{\nu}$ is experimentally observed, then it is likely to observe the decay mode $\pi^0 e^+$, too, in sharp contrast to the case of the minimal SUSY $SU(5)$ GUT.

V. CONCLUSION

Flavor symmetry can play important rolls in supersymmetric models [59]. We have investigated the SUSY contributions to FCNCs and to proton decay in a supersymmetric extension of the SM based on a binary dihedral family group Q_6 . We have seen that the discrete low energy flavor symmetry Q_6 can be an alternative to the universality assumption of the soft supersymmetry breaking parameters. That is, the existence of a hidden sector, in which supersymmetry is assumed to be broken in a flavor blind manner, is not indispensable in this model. Therefore, a variety of supersymmetry breaking mechanisms may become phenomenologically viable.

It has turned out from our analysis on FCNCs that the degeneracy requirement of the soft scalar masses of the left-handed squarks in this model can be significantly relaxed. This has a considerable effect on the gluino-mediated one-loop amplitudes on proton decay. In most of the previous calculations, the degeneracy was assumed so that the gluino contributions are cancelled with each other, which implies that the wino contributions are the most dominant contributions. We have found that the non-degenerate squarks can change the decay rate in the charged lepton modes by an order of magnitude. We have also found that in

the lowest order approximation there is only one independent coefficient for dimension-five operators that lead to proton decay. Consequently, the relative partial decay rates in this approximation are fixed, reflecting the flavor structure dictated by Q_6 .

Our main finding is that Q_6 flavor symmetry acts in such a way that the smallness of $(V_{\text{MNS}})_{e3}$, the suppression of $\mu \rightarrow e + \gamma$, and the smallness of $B(p \rightarrow K^0(\pi^0) + \mu^+)/B(p \rightarrow K^0(\pi^0) + e^+)$ have the same origin; the electron is much lighter than the muon and the tau. They in fact vanish in the $m_e \rightarrow 0$ limit.
